1 Support Vector Machines (SVM) Introduction

1.1 Required R Packages

We will be using the R packages of:

- tidyverse for data manipulation and visualization
- e1071 for the svm() functions

1.2 Example

1.3 SVM as Loss + Penalty

Training Data: $\{(\tilde{y}_i, \mathbf{x}_i)\}_{i=1}^n$

- $\tilde{y}_i \in \{-1, +1\}$ $\mathbf{x}_i^{\mathsf{T}} = [x_{i1}, x_{i2}, \dots, x_{in}] \in \mathbb{R}^p$

Predictor Function: f(x)

- Linear: $f(\mathbf{x}; \beta) = \beta_0 + \sum_{j=1}^p x_j \beta_j$ Basis Expansion: $f(\mathbf{x}; \beta) = \beta_0 + \sum_{j=1}^d h_j(\mathbf{x}) \beta_j$ $h_j(\mathbf{x})$ transforms the raw x vector

 - Polynomial example: $h_1(\mathbf{x}) = x_1$, $h_2(\mathbf{x}) = x_1^2$, $h_3(\mathbf{x}) = x_2$, $h_4(\mathbf{x}) = x_2^2$, $h_5(\mathbf{x}) = x_1x_2$
 - This is the connection to kernels that we will discuss later
- Let $f_i = f(\mathbf{x}_i)$

Classification:

- If $\hat{f}_i \geq 0$, then label as class +1
- If $\hat{f}_i < 0$, then label as class -1

Loss Function: Hinge Loss

$$L(\tilde{y}_i, f_i) = \max\{0, 1 - \tilde{y}_i f_i\}$$

Penalty Function: Ridge Penalty

$$P_{\lambda}(\beta) = \frac{\lambda}{2} \sum_{j=1}^{d} \beta_j^2$$
$$= \lambda \|\beta\|^2 / 2$$

• This should have you thinking that the x's should be scaled!

Summary of SVM

1. Estimate model parameters β

$$\hat{\beta}_{\lambda} = \underset{\beta}{\operatorname{arg\,min}} \left\{ \sum_{i=1}^{n} \max\{0, 1 - \tilde{y}_{i} f_{i}(\beta)\} + \lambda \|\beta\|^{2} / 2 \right\}$$

$$= \underset{\beta}{\operatorname{arg\,min}} \left\{ \operatorname{Hinge\,Loss}(\beta) + \lambda \operatorname{Penalty}(\beta) \right\}$$

- 2. Label Class +1 if $\hat{f}_i \geq 0$, else label Class -1
 - This implicitly assumes a 0-1 loss (or equal cost FP and FN)
 - \bullet More generally, use threshold t that considers the costs of FP and FN
- 3. **Tuning Parameters**: besides the λ , SVM will also have tuning parameters related to the kernels (more to come on this).

1.4 SVM vs. Logistic Regression

The linear SVM is actually very similar to Logistic Regression (with Ridge Penalty).

Let $f_i(\beta) = \beta_0 + \sum_{j=1}^p x_j \beta_j$ be the log-odds.

- We also referred to this as $\gamma(\mathbf{x}_i)$ in previous notes.
- 1. Estimate model parameters β
 - This assumes standardized x's

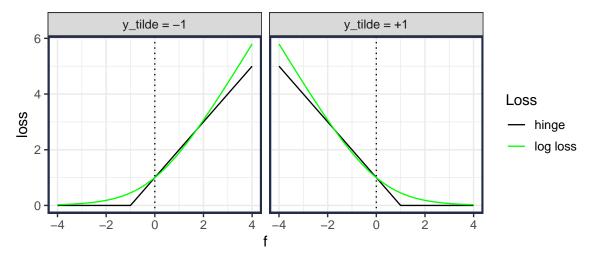

$$\hat{\beta}_{\lambda} = \underset{\beta}{\operatorname{arg\,min}} \left\{ \sum_{i=1}^{n} \log \left(1 + \exp \left(-\tilde{y}_{i} f_{i}(\beta) \right) \right) + \lambda \left\| \beta \right\|^{2} / 2 \right\}$$

$$= \underset{\beta}{\operatorname{arg\,min}} \left\{ \operatorname{Log\,Loss}(\beta) + \lambda \operatorname{Penalty}(\beta) \right\}$$

- 2. Label Class +1 if $\hat{f}_i \geq t$, else label Class -1
 - ullet For some threshold t that considers the costs of FP and FN
 - If Cost(FP) = Cost(FN), the set t = 0, which is equivalent to p(x) = 1/2

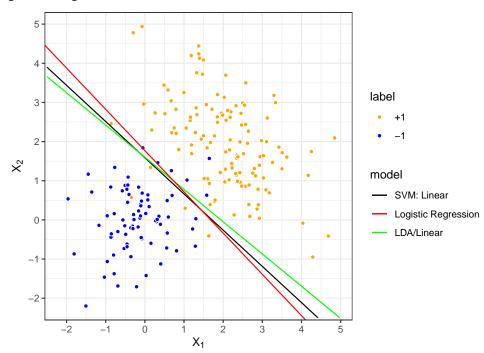

Details of the Logistic Regression Loss Function

Note	

The Log-Loss has been scaled so it equals the Hinge Loss at f=0.

1.5 Example: Compare Linear Classifiers

1.6 Three Representations of the Optimization Problem

1. Penalized optimization

$$\begin{split} \hat{\beta} &= \operatorname*{arg\,min}_{\beta} \left\{ \operatorname{Loss}(\beta) + \lambda \ \operatorname{Penalty}(\beta) \right\} \\ &= \operatorname*{arg\,min}_{\beta} \left\{ C \ \operatorname{Loss}(\beta) + \operatorname{Penalty}(\beta) \right\} \end{split}$$

DS 6030 | Fall 2021

- where $C = \frac{1}{\lambda} > 0$ is an alternative strength of penalty
- In SVM, C is referred to as the cost
- 2. Constraint on Penalty

$$\begin{split} \hat{\beta} &= \mathop{\arg\min}_{\beta} \ \operatorname{Loss}(\beta) \quad \text{ subject to } \ \operatorname{Penalty}(\beta) \leq t \\ &= \mathop{\arg\min}_{\beta: \ \operatorname{Penalty}(\beta) \leq t} \ \operatorname{Loss}(\beta) \end{split}$$

3. Constraint on Loss

$$\begin{split} \hat{\beta} &= \mathop{\arg\min}_{\beta} \ \operatorname{Penalty}(\beta) \qquad \text{subject to} \ \operatorname{Loss}(\beta) \leq M \\ &= \mathop{\arg\min}_{\beta: \ \operatorname{Loss}(\beta) \leq M} \ \operatorname{Penalty}(\beta) \end{split}$$

Note

There is a one-to-one relationship between all tuning parameters: λ , C, t, M.

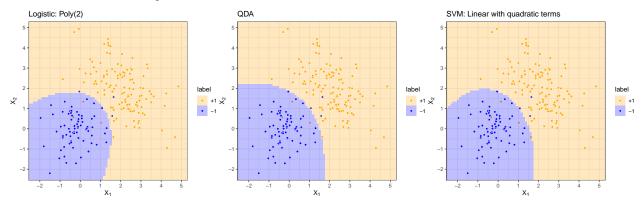

2 Kernels and Non-linear SVM

2.1 Basis Expansion

- Linear: $f(\mathbf{x}; \beta) = \beta_0 + \sum_{j=1}^p x_j \beta_j$
- Basis Expansion: $f(\mathbf{x}; \beta) = \beta_0 + \sum_{j=1}^d h_j(\mathbf{x})\beta_j$
 - $h_j(\mathbf{x})$ transforms the raw \mathbf{x} vector

2.1.1 Polynomial Expansion: Quadratic Terms

- Polynomial example: $h_1(\mathbf{x}) = x_1, h_2(\mathbf{x}) = x_1^2, h_3(\mathbf{x}) = x_2, h_4(\mathbf{x}) = x_2^2, h_5(\mathbf{x}) = x_1x_2$
- $f(\mathbf{x}; \beta) = \beta_0 + \sum_{j=1}^5 h_j(\mathbf{x})\beta_j$

2.2 Alternative (Dual) Formulation

It turns out that the SVM solution for the model coefficients β can be written as

$$\hat{\beta}_j = \sum_{i=1}^n \hat{\alpha}_i \, y_i \, h_j(\mathbf{x}_i)$$

- See ESL Eq. 12.17 if you are interested in the details.
- In this reformulation, the $\{\hat{\alpha}_i\}_{i=1}^n$ become the model parameters.
 - There is one model parameter for each observation!
 - $-0 \le \alpha_i \le C \text{ (or } 0 \le \alpha_i \le \frac{1}{\lambda})$
 - But SVM will force most values to 0.
 - The observations with $\alpha_i > 0$ are called the *support vectors*
 - * So the entire SVM model is a function of the support vectors only!
 - * The support vectors are the observations on the wrong side of the margin.
- The decision function $\hat{f}(\mathbf{x})$ can be re-written

$$\hat{f}(\mathbf{x}) = f(\mathbf{x}; \hat{\beta})$$

$$= \hat{\beta}_0 + \sum_{j=1}^d h_j(\mathbf{x}) \hat{\beta}_j$$

$$= \hat{\beta}_0 + \sum_{j=1}^d h_j(\mathbf{x}) \left[\sum_{i=1}^n \hat{\alpha}_i y_i h_j(\mathbf{x}_i) \right]$$

$$= \hat{\beta}_0 + \sum_{i=1}^n \hat{\alpha}_i y_i \left[\sum_{j=1}^d h_j(\mathbf{x}) h_j(\mathbf{x}_i) \right]$$

$$= \hat{\beta}_0 + \sum_{i=1}^n \hat{\alpha}_i y_i K(\mathbf{x}, \mathbf{x}_i)$$

where

$$K(\mathbf{x}, \mathbf{x}_i) = \sum_{j=1}^d h_j(\mathbf{x}) h_j(\mathbf{x}_i) = \langle h(\mathbf{x}), h(\mathbf{x}_i) \rangle$$

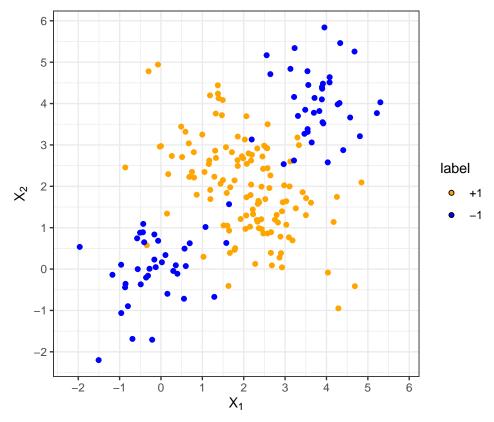

is called a **kernel** and measures the inner product, or *similarity* between x and x_i (observation i).

2.3 SVM in R

- The svm() function from the e1071 package can implement SVM.
 - There is also a helpful tune.svm() to help you select the tuning parameters.
- The ISLR Lab in Section 9.6 has example R code.

2.4 Kernels

To help illustrate the difference between different kernels, let's look at slightly different data that won't be easy to classify using linear classifiers.

Three popular kernels (but there are many more) are the linear, polynomial, and radial basis

2.4.1 Linear Kernel

The linear kernel is

$$K(\mathbf{x},\mathbf{u}) = \sum_{j=1}^p \mathbf{x}_j \mathbf{u}_j = \langle \mathbf{x},\mathbf{u} \rangle$$
 SVM: linear kernel (cost = 1)

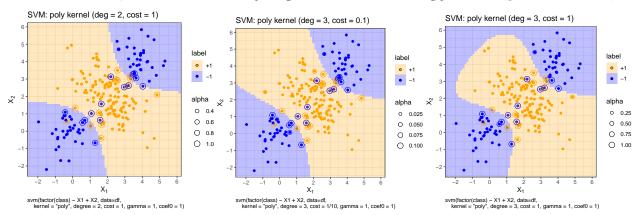

$$\hat{f}_{linear}(\mathbf{u}) = \hat{\beta}_0 + \sum_{i=1}^n \hat{\alpha}_i y_i K(\mathbf{x}_i, \mathbf{u})$$
$$= \hat{\beta}_0 + \sum_{i=1}^n \hat{\alpha}_i y_i \left(\sum_{j=1}^p \mathbf{x}_{ij} \mathbf{u}_j \right)$$

2.4.2 Polynomial Kernel

The polynomial kernel of degree deg is

$$K(\mathbf{x}, \mathbf{u}) = \left(1 + \sum_{j=1}^{p} \mathbf{x}_j \mathbf{u}_j\right)^{\text{deg}}$$

Note: in R, the 'svm()' function from 'e1071' package includes two other tuning parameters (gamma and coef0)

$$\hat{f}_{\text{poly}}(\mathbf{u}) = \hat{\beta}_0 + \sum_{i=1}^n \hat{\alpha}_i \, y_i \, K(\mathbf{x}_i, \mathbf{u})$$
$$= \hat{\beta}_0 + \sum_{i=1}^n \hat{\alpha}_i \, y_i \, \left(1 + \sum_{j=1}^p \mathbf{x}_j \mathbf{u}_j \right)^{\text{deg}}$$

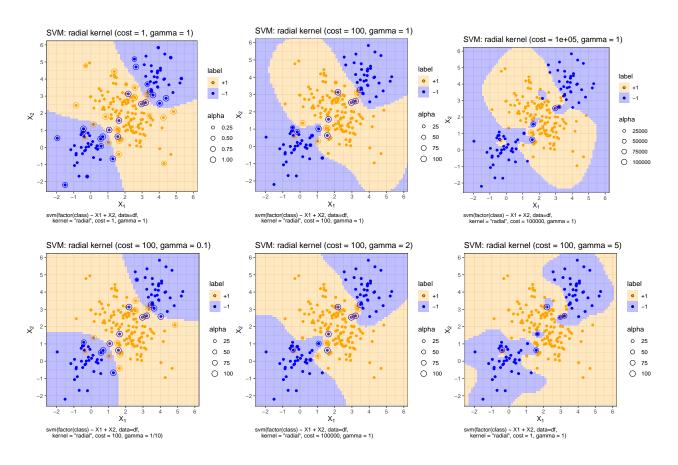

2.4.3 Radial Basis Kernel

The Radial Basis Kernel with parameter γ (gamma) is

$$K(\mathbf{x}, \mathbf{u}) = \exp\left(-\gamma \sum_{j=1}^{p} (\mathbf{x}_j - \mathbf{u}_j)^2\right)$$
$$= \exp\left(-\gamma \operatorname{dist}^2(\mathbf{x}, \mathbf{u})\right)$$

where $dist^2(\mathbf{x}, \mathbf{u})$ is the squared Euclidean distance between \mathbf{x} and \mathbf{u} .

- The Radial Basis kernel is large for test observations close to training observations.
- Notice that both cost and gamma are influential tuning parameters.

$$\hat{f}_{\text{radial}}(\mathbf{u}) = \hat{\beta}_0 + \sum_{i=1}^n \hat{\alpha}_i \, y_i \, K(\mathbf{x}_i, \mathbf{u})$$
$$= \hat{\beta}_0 + \sum_{i=1}^n \hat{\alpha}_i \, y_i \, \exp\left(-\gamma \, dist^2(\mathbf{x}, \mathbf{u})\right)$$

2.5 Unbalanced Data

Two primary approaches:

- 1. Use weights corresponding to prior class probabilities
 - See the class.weights argument in ?svm
- 2. Use a threshold on the score
 - E.g., choose label = +1 if: $\hat{f}(\mathbf{x}) > t$
 - ullet The \hat{f} are the decision.values output of predict.svm
 - Its an attribute of the returned object
